

C partial signalling

the map is sent only where the predictor is worst, and the price is sent always

Both sides — the encoder runs a REPLICA of the decoder's predictor

only these are sent

Regret is not spread out. At qp0 its Gini over tiles is 0.95 and the worst tenth — 3.4 tiles of 33 — carries 99.8% of it, so a handful of overrides reaches most of what B gave up.

$\rho = 0$ is exactly B and $\rho = 1$ is exactly A. The same channel carries the per-frame multiplier that makes B guarantee.

at $\rho = 0.1$, qp0

33.72%

map bits at that point

26 bits/frame

tiles overridden

3.4 of 33
